SAFETY

Managing Naturally Occurring Radioactive Material

What is a NORM?

Naturally occurring radioactive material (NORM) refers to radioactive substances that exist in the environment and originate from the Earth's crust. Unstable elements break down, releasing energy as radiation. Naturally occurring radioactive materials include uranium, thorium, potassium and carbon. These substances and their radioactive decay products can become concentrated through industrial processes and pose a hazard.

Ionizing Radiation Types

- Alpha particles: Large and do not pass through paper or the skin on the outside of your body. Found in metallic films, scale and sludge.
- Beta particles: High-energy electrons that can penetrate skin and thin materials, including skin.
- Gamma rays: Highly penetrating radiation that can pass through most materials, including the human body, buildings, vessels and piping. Typically dissipates quickly.

NORM in the Energy Industry

NORM naturally occurs in oil and gas formations and can accumulate in processing equipment. It appears as radon gas, in solid form (sludge and scale), dissolved in liquids (such as produced water) or embedded in metals. Radioactive isotopes are released or present throughout oil and gas activities, including extraction and production.

NORM in Canada

NORM has been identified in several regions across Canada, including northern, central and southeastern Alberta, northern and southern British Columbia, southern Saskatchewan, and offshore Atlantic wells. Its presence and concentration can vary depending on the age and geographical formation.

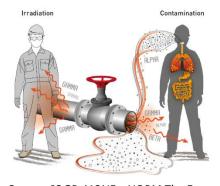

Exposure

Workers may be exposed to NORM through:

- Irradiation: External exposure.
- Contamination: Internal exposure from inhaling and ingesting sources.

Managing exposure involves:

- Minimizing time spent in contaminated areas.
- Maximizing distance from sources.
- Using proper personal protective equipment.

SAFETY

Managing Naturally Occurring Radioactive Material

Activities where NORM Exposure may Occur:

I		
Activities/Tasks		Radiation
		Exposure Type
•	Cleaning vessels and	Inhalation and
	tanks, valve seats	ingestion of
	(e.g., disturbing scale	radium, thorium
	and sludge)	and lead-210—
•	Changing orifice and	alpha and beta
	conditioning plates	particles but not
	and filters	limited to these
•	Removing downhole	
	equipment (e.g.,	
	tubing, pumps)	
•	Welding on	
	contaminated	
	surfaces	
•	Others include	
	pigging, internal	
	inspection, and work	
	with refractory	
	brick/products	
•	Working near active	External gamma
	process equipment	radiation (body
		penetration)

Health Effects

Ionizing radiation from NORM can increase the risk of cancers such as lung cancer and leukemia. The specific risk depends on the type of radiation and conditions of exposure.

NORM Measurement and Exposure

NORM is measured in:

- Becquerels (Bq): Indicates the activity or total radiation emitted.
- Micro-Sieverts (μ Sv): Represents the effective dose and associated risk to humans.

Follow the ALARP principle (As Low As Reasonably Practicable) to manage exposure. Controls include:

- Increasing distance.
- Reducing time of exposure.
- Applying shield.
- Minimizing aerosolization of NORM.
- Using PPE as the last line of defense to prevent internal contamination (e.g., respiratory protection such as a half-face respirator, gloves, disposable full-body coverall).

Apply the hierarchy of controls in your management of NORM.

Detection and Control

A management or control plan can assist with monitoring and controlling the risk of NORM exposure. Ensure that your plan also complies with the relevant legislation and regulations.
